

Analyzing Snapshot Isolation

Andrea Cerone Alexey Gotsman

IMDEA Software Institute

PODC 2016

presented by Dima Kuznetsov

Agenda

1 Introduction

2 Snapshot Isolation

- Definitions
- Dependency Graphs
- Characterization

3 Static Analysis

- Transaction Chopping
- Robustness

- We focus on *Snapshot Isolation* presented in the last talk
- ... same context of DBMS and transactional memory systems

- DBMS typically offer various guarantees for transaction management
- Each mode exhibits different *anomalies*
- Stronger modes exhibit less anomalies at expense of performance
 - Stronger guarantees incur more overhead on the DBMS side
 - Less allowed behaviors → more concurrent transactions expected to abort

From Wikipedia¹:

*A transaction executing under **snapshot isolation** appears to operate on a personal snapshot of the database, taken at the start of the transaction. When the transaction concludes, it will successfully commit only if the values updated by the transaction have not been changed externally since the snapshot was taken.*

¹https://en.wikipedia.org/wiki/Snapshot_isolation#Definition 

We'll focus on ***strong session Snapshot Isolation***:

Transactions are grouped into sessions, a transaction's snapshot is expected to include *all preceding transactions* of the same session.

1 Introduction

2 Snapshot Isolation

- **Definitions**
- Dependency Graphs
- Characterization

3 Static Analysis

- Transaction Chopping
- Robustness

We'll use a lot of notation similar to Daniel's talk two weeks ago

- $Obj = \{x, y, \dots\}$ - objects in the data set
- $Event = \{e, f, \dots\}$ - transaction events
- $Op = \{read(x, n), write(x, n) \mid x \in Obj, n \in \mathbb{Z}\}$
- $op : Event \rightarrow Op$

Definition

A **transaction** T, S, \dots is a pair (E, po) where $E \subseteq \text{Event}$ is a *finite*, non-empty set of events and **program-order** $po \subseteq E \times E$ is a total order.

Where ...

- *total order* is a transitive and irreflexive relation that orders all pairs

Definition

A **history** is a pair $\mathcal{H} = (\mathcal{T}, SO)$ where \mathcal{T} is a finite set of transactions with disjoint set of events and the **session-order** $SO \subseteq \mathcal{T} \times \mathcal{T}$ is a union of total orders defined on disjoint subsets of \mathcal{T} , which correspond to transactions in different sessions.

Definition

An **abstract execution** is a tuple $\mathcal{X} = (\mathcal{T}, SO, VIS, CO)$, where (\mathcal{T}, SO) is a history and the **visibility** and **commit order** $VIS, CO \subseteq \mathcal{T} \times \mathcal{T}$ are such that $VIS \subseteq CO$ and CO is total.

Assumptions:

- All transactions commit (aborted ones do not affect the history)
- All histories are finite (no infinite computations)

- We'll use $(T, S) \in VIS$ and $T \xrightarrow{VIS} S$ interchangeably for VIS and other relations.
- For $\mathcal{H} = (\mathcal{T}, SO)$ we will shorten $(\mathcal{T}, SO, VIS, CO)$ to (\mathcal{H}, VIS, CO)
- For $\mathcal{H} = (\mathcal{T}, SO)$ and other tuples, we'll use $\mathcal{T}_{\mathcal{H}}$ to denote that \mathcal{T} is part of the tuple \mathcal{H}

For the relations defined in abstract execution:

- $T \xrightarrow{VIS} S$ means that T is included in S 's snapshot.
- $T \xrightarrow{CO} S$ means that T is committed before S .
- $VIS \subseteq CO$ makes sure that snapshots include only already committed transactions.

We'll now try to define *snapshot isolation* and *serializability* in terms of **consistency axioms**:

$$ExecSI = \{\mathcal{X} \mid \mathcal{X} \models \text{INT} \wedge \text{EXT} \wedge \text{SESSION} \wedge \\ \text{PREFIX} \wedge \text{NOCONFLICT}\}$$

$$ExecSER = \{\mathcal{X} \mid \mathcal{X} \models \text{INT} \wedge \text{EXT} \wedge \text{SESSION} \wedge \text{TOTALVIS}\}$$

$$HistSI = \{\mathcal{H} \mid \exists VIS, CO : (\mathcal{H}, VIS, CO) \in ExecSI\}$$

$$HistSER = \{\mathcal{H} \mid \exists VIS, CO : (\mathcal{H}, VIS, CO) \in ExecSER\}$$

Definition (Internal consistency)

INT - ensures that a read event e on object x returns the same value a as the last write or read on x in the same transaction.

$$\forall (E, po) \in \mathcal{T}. \forall e \in E. \forall x, n :$$

$$\begin{aligned} op(e) = read(x, n) \wedge \{f \mid op(f) = _ (x, _) \wedge f \xrightarrow{po} e\} \neq \emptyset \Rightarrow \\ op\left(\max_{po}\{f \mid op(f) = _ (x, _) \wedge f \xrightarrow{po} e\}\right) = _ (x, n) \end{aligned}$$

Where ...

- $\max_R(A) = \{b \mid \forall b \in A : a = b \vee (a, b) \in R\}$
- $\min_R(A) = \{a \mid \forall b \in A : a = b \vee (a, b) \in R\}$

Definition (External consistency)

EXT - ensures that if $T \vdash \text{read}(x, n)$ then the value is taken from the last visible transaction that wrote to x according to commit order.

$\forall T \in \mathcal{T}. \forall x, n :$

$$T \vdash \text{read}(x, n) \Rightarrow \max_{CO} \left(\text{VIS}^{-1}(T) \cap \text{WriteTx}_x \right) \vdash \text{write}(x, n)$$

Where ...

- $T \vdash \text{read}(x, n)$ if T reads from x and n is the value of x at the first read.
- $T \vdash \text{write}(x, n)$ if T writes to x and n is the final value of x .
- $R^{-1}(a) = \{b \mid (b, a) \in R\}$
- $\text{WriteTx}_x = \{T \mid T \vdash \text{write}(x, _)\}$

Definition (Session visibility)

SESSION - requires a snapshot to include all preceding transactions of the same session.

$$SO \subseteq VIS$$

(a) Session guarantees.

Example

T_1 ordered after T_2 by *SO* (therefore by *VIS* and *CO*), T_2 must read 1 from x .

Definition (Prefix)

PREFIX - ensures that if snapshot taken by T includes S , then it includes all transactions committed before S as well.

$$CO; VIS \subseteq VIS$$

Where ...

- $R_1; R_2 = \{(a, b) \mid \exists c : (a, c) \in R_1 \wedge (c, b) \in R_2\}$

The **long-fork** anomaly is prevented by PREFIX axiom:

(c) Long fork.

Example

Consider T_1 commits before T_2 , then since T_4 's snapshot contains T_2 (due to *VIS*), it must include T_1 as well

Definition (No conflict check)

NOCONFLICT - ensures that for any two transactions writing to the same object, one has to be aware of the other.

$$\forall T, S \in \mathcal{T}. \forall x, n.$$

$$(T, S \in \text{WriteTx}_x \wedge T \neq S) \Rightarrow \left(T \xrightarrow{\text{VIS}} S \vee S \xrightarrow{\text{VIS}} T \right)$$

The **lost-update** anomaly is prevented by NOCONFLICT axiom:

(b) Lost update.

Example

T_1 and T_2 concurrently increment `acct` object, but neither $T_1 \xrightarrow{VIS} T_2$ nor $T_2 \xrightarrow{VIS} T_1$.

Definition (Total visibility)

TOTALVIS - requires total order on the visibility relation, giving us *serializability* of transactions.

$$VIS = CO$$

The **write-skew** anomaly allowed by Snapshot Isolation is prevented by TOTALVIS axiom:

(d) Write skew. Initially $\text{acct1} = \text{acct2} = 60$.

T_1

```
if (acct1 + acct2 > 100)
  acct1 := acct1 - 100
```

$\text{read}(\text{acct1}, 60) \rightarrow \text{read}(\text{acct2}, 60) \rightarrow \text{write}(\text{acct1}, -40)$

RW

RW

T_2

```
if (acct1 + acct2 > 100)
  acct2 := acct2 - 100
```

$\text{read}(\text{acct1}, 60) \rightarrow \text{read}(\text{acct2}, 60) \rightarrow \text{write}(\text{acct2}, -40)$

Example

With TOTALVIS, either T_1 or T_2 would have to be aware of the other, and we won't be able to read stale values.

1 Introduction

2 Snapshot Isolation

- Definitions
- **Dependency Graphs**
- Characterization

3 Static Analysis

- Transaction Chopping
- Robustness

- Our goal now is to characterize SI in terms of dependencies between transactions.
- Then we'll be able to decide whether SI allows a given history by looking for appropriate dependencies.

Definition

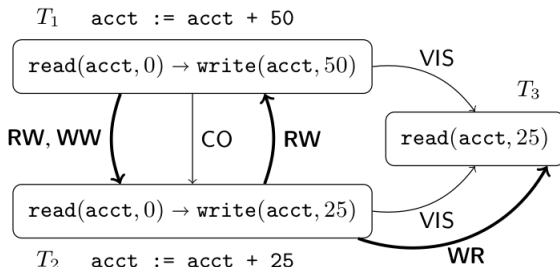

A **dependency graph** is a tuple $\mathcal{G} = (\mathcal{T}, SO, WR, WW, RW)$, where (\mathcal{T}, SO) is a history and:

- $WR: Obj \rightarrow 2^{\mathcal{T} \times \mathcal{T}}$ is such that:
 - $\forall T, S. \forall x. T \xrightarrow{WR(x)} S \Rightarrow \exists n. T \neq S \wedge T \vdash \text{write}(x, n) \wedge S \vdash \text{read}(x, n)$
 - $\forall S \in \mathcal{T}. \forall x. S \vdash \text{read}(x, _) \Rightarrow \exists T. T \xrightarrow{WR(x)} S$
 - $\forall T, T', S \in \mathcal{T}. \forall x. \left(T \xrightarrow{WR(x)} S \wedge T' \xrightarrow{WR(x)} S \right) \Rightarrow T = T'$
- $WW: Obj \rightarrow 2^{\mathcal{T} \times \mathcal{T}}$ is such that for every $x \in Obj$, $WW(x)$ is a total order on the set $WriteTx_x$.
- $RW: Obj \rightarrow 2^{\mathcal{T} \times \mathcal{T}}$ is derived from WR and WW such that
$$T \xrightarrow{RW(x)} S \Leftrightarrow T \neq S \wedge \exists T'. T' \xrightarrow{WR(x)} T \wedge T' \xrightarrow{WW(x)} S$$

Informally,

- $T \xrightarrow{WR(x)} S$ means that S reads T 's write to x .
- $T \xrightarrow{WW(x)} S$ means that S overwrites T 's write to x .
- $T \xrightarrow{RW(x)} S$ means that S overwrites the write to x read by T .

(b) Lost update.

Example

- T_3 reads `acct` from T_2 's write $\Rightarrow T_2 \xrightarrow{WR(acct)} T_3$
- T_2 overwrites `acct` written in $T_1 \Rightarrow T_1 \xrightarrow{WW(acct)} T_2$
- Both T_1 and T_2 overwrite `acct`'s initial value read by both,
 $T_1 \xrightarrow{RW(acct)} T_2$ and $T_2 \xrightarrow{RW(acct)} T_1$.

Definition

Consider execution $\mathcal{X} = (\mathcal{T}, SO, VIS, CO)$, for $x \in Obj$ we define:

- **read-dependency** $WR_{\mathcal{X}}(x)$ as:

$$T \xrightarrow{WR_{\mathcal{X}}(x)} S \Leftrightarrow \\ S \vdash read(x, n) \wedge T = \max_{CO} \left(VIS^{-1}(S) \cap WriteTx_x \right)$$

- **write-dependency** $WW_{\mathcal{X}}(x)$ as:

$$T \xrightarrow{WW_{\mathcal{X}}(x)} S \Leftrightarrow T \xrightarrow{CO} S \wedge T, S \in WriteTx_x$$

- **anti-dependency** $RW_{\mathcal{X}}(x)$ as:

$$T \xrightarrow{RW_{\mathcal{X}}(x)} S \Leftrightarrow T \neq S \wedge \exists T'. T' \xrightarrow{WR_{\mathcal{X}}(x)} T \wedge T' \xrightarrow{WW_{\mathcal{X}}(x)} S$$

Proposition

For any $\mathcal{X} \in \text{ExecSI}$,

$$\text{graph}(\mathcal{X}) = (\mathcal{T}_{\mathcal{X}}, SO_{\mathcal{X}}, WR_{\mathcal{X}}, WW_{\mathcal{X}}, RW_{\mathcal{X}})$$

is a dependency graph.

Proof

By showing $\text{graph}(\mathcal{X})$ satisfies all requirements of a dependency graph.

1 Introduction

2 Snapshot Isolation

- Definitions
- Dependency Graphs
- **Characterization**

3 Static Analysis

- Transaction Chopping
- Robustness

We'll show that SI is characterized by dependency graphs that contain only cycles with at least two adjacent anti-dependency edges.

Theorem

Let

$$\text{GraphSER} = \{ \mathcal{G} \mid (\mathcal{T}_{\mathcal{G}} \models \text{INT}) \\ ((\text{SO}_{\mathcal{G}} \cup \text{WR}_{\mathcal{G}} \cup \text{WW}_{\mathcal{G}} \cup \text{RW}_{\mathcal{G}}) \text{ is acyclic}) \}$$

Then

$$\text{HistSER} = \{ \mathcal{H} \mid \exists \text{WR}, \text{WW}, \text{RW}. \\ (\mathcal{H}, \text{WR}, \text{WW}, \text{RW}) \in \text{GraphSER} \}$$

In other words, execution is serializable if it can be extended into an acyclic dependency graph.

Theorem

Let

$$\text{GraphSI} = \{ \mathcal{G} \mid (\mathcal{T}_{\mathcal{G}} \models \text{INT}) \wedge \\ \left(\left((SO_{\mathcal{G}} \cup WR_{\mathcal{G}} \cup WW_{\mathcal{G}}) ; RW_{\mathcal{G}}^? \right) \text{ is acyclic} \right) \}$$

Then

$$\text{HistSI} = \{ \mathcal{H} \mid \exists WR, WW, RW. (\mathcal{H}, WR, WW, RW) \in \text{GraphSI} \}$$

Where ...

- $R^? = R \cup \{(a, a) \mid a \in A\}$

The relation $(SO_{\mathcal{G}} \cup WR_{\mathcal{G}} \cup WW_{\mathcal{G}}); RW_{\mathcal{G}}^?$ includes edges of the following form:

- SO
- WR
- WW
- $SO; RW$
- $WR; RW$
- $WW; RW$

If there is a cycle in \mathcal{G} , it:

- cannot be composed only of $SO \cup WR \cup WW$ edges, otherwise it is a cycle in CO
- cannot contain only non-adjacent anti-dependency, otherwise above relation is cyclic.

\Rightarrow any cycle has to have at least two adjacent anti dependencies.

The latter type of cycles are disallowed under SI, they allow *long fork* and *lost update* anomalies.

Prohibited under SI:

(b) Lost update.

(c) Long fork.

contain cycles without adjacent anti dependencies.

(d) Write skew. Initially $\text{acct1} = \text{acct2} = 60$.

T_1

```
if (acct1 + acct2 > 100)
  acct1 := acct1 - 100
```

read(acct1, 60) → read(acct2, 60) → write(acct1, -40)

RW ↙

↗ RW

T_2

```
if (acct1 + acct2 > 100)
  acct2 := acct2 - 100
```

read(acct1, 60) → read(acct2, 60) → write(acct2, -40)

- Prohibited under **serializability**, and has a dependency graph cycle $T_1 \xrightarrow{RW} T_2 \xrightarrow{RW} T_1$.
- However, allowed under **SI**

To prove the previous theorem we'll show a stronger result:

Theorem

1 **Soundness:**

$$\forall \mathcal{G} \in \text{GraphSI}. \exists \mathcal{X} \in \text{ExecSI}. \text{graph}(\mathcal{X}) = \mathcal{G}$$

2 **Completeness:**

$$\forall \mathcal{X} \in \text{ExecSI}. \text{graph}(\mathcal{X}) \in \text{GraphSI}$$

Completeness closely follows from existing results². We will focus on *soundness*.

²Making Snapshot Isolation Serializable, 2005, A. Fekete et al

Objective

Soundness:

$$\forall \mathcal{G} \in \text{GraphSI}. \exists \mathcal{X} \in \text{ExecSI}. \text{graph}(\mathcal{X}) = \mathcal{G}$$

Proof sketch

- Construct a basic **pre-execution** from \mathcal{G}
- Iteratively extend it until satisfies execution definition

Definition

A tuple $\mathcal{P} = (\mathcal{T}, SO, VIS, CO)$ is a **pre-execution** if it satisfies all the conditions of being an *execution*, except CO is a *strict partial order* that may not be total.

Where ...

- *strict partial order* is a transitive and irreflexive relation

Definition

We let $PreExecSI$ be the set of pre-executions satisfying the SI axioms:

$$PreExecSI = \{\mathcal{P} \mid \mathcal{P} \models INT \wedge EXT \wedge SESSION \wedge \\ PREFIX \wedge NOCONFLICT\}$$

- Consider $\mathcal{G} = (\mathcal{H}, WR, WW, RW)$, let $\mathcal{P} = (\mathcal{H}, VIS, CO)$ a respective pre-execution.
- VIS, CO must hold the following to conform with \mathcal{G} and satisfy *PreExecSI*:

$SO \cup WR \cup WW \subseteq VIS$ VIS must conform with read/write dependencies of \mathcal{G} and with SO to hold SESSION axiom.

$CO; VIS \subseteq VIS$ to ensure PREFIX axiom.

$VIS \subseteq CO$ to conform with SI definition - only committed transactions in snapshots.

$CO; CO$ transitivity of CO

$VIS; RW \subseteq CO$ to ensure EXT axiom

Lemma

Let $\mathcal{G} = (\mathcal{T}, SO, WR, WW, RW)$ be a dependency graph, for any relation $R \subseteq \mathcal{T} \times \mathcal{T}$, the relations

$$VIS = (((SO \cup WR \cup WW); RW^?) \cup R)^*;$$
$$(SO \cup WR \cup WW)$$

$$CO = (((SO \cup WR \cup WW); RW^?) \cup R)^+$$

are a solution to the system of inequalities in the previous slide. They also are the smallest solution to the system for which $R \subseteq CO$.

Where...

- R^+ a transitive closure of R
- R^* a transitive and reflexive closure of R

Proof outline.

Let $\mathcal{G} = (\mathcal{T}, SO, WR, WW, RW) \in \text{GraphSI}$

- Define \mathcal{P}_0 derived from the last lemma by fixing $R_0 = \emptyset$.
- Construct $\{\mathcal{P}_i = (\mathcal{T}, SO, VIS_i, CO_i)\}_{i=0}^n$ series of pre-executions.
- While CO_i is not total:
 - Pick arbitrary pair T, S not ordered by CO_i
 - $R_{i+1} = R_i \cup \{(T, S)\}$
 - Use the lemma with $R = R_{i+1}$ to derive VIS_{i+1}, CO_{i+1} (and thus \mathcal{P}_{i+1})
- Let $\mathcal{X} = \mathcal{P}_n$ as CO_n is now total.

1 Introduction

2 Snapshot Isolation

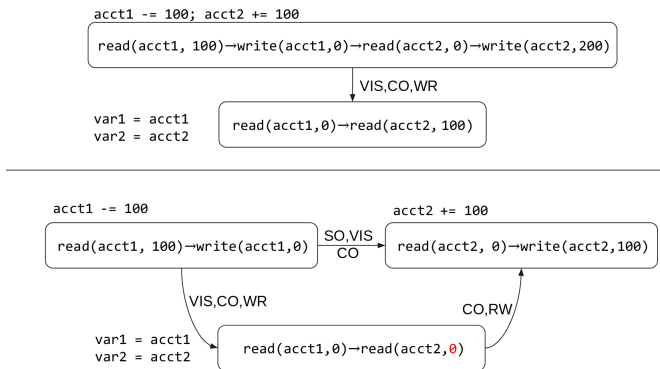

- Definitions
- Dependency Graphs
- Characterization

3 Static Analysis

- Transaction Chopping
- Robustness

Transaction Chopping under SI:

- We'll derive a static analysis that checks if transactions can be chopped into smaller sessions
- The analysis will suggest an optimized program provided any execution with chopped transactions does not exhibit new behaviors.

Example

Given the above graph, can we chop the top transaction into 2 parts?

No... bottom transaction will be able to observe intermittent state.

Example

What if we decouple the reads into separate sessions?

Each read is allowed to observe the transfer in any order, no new observable behaviors.

Definition

For history \mathcal{H} , let

$$\approx_{\mathcal{H}} = SO_{\mathcal{H}} \cup SO_{\mathcal{H}}^{-1} \cup \{(T, T) \mid T \in \mathcal{T}_{\mathcal{H}}\}$$

the equivalence relation grouping transactions from same session.

Definition

Let $\boxed{T}_{\mathcal{H}} = (E, po)$ where $E = (\bigcup \{E_S \mid S \approx_{\mathcal{H}} T\})$ and

$$po = \{(e, f) \mid \left(\exists S. e, f \in E_S \wedge e \xrightarrow{po_S} f \wedge S \approx_{\mathcal{H}} T \right) \vee \\ \left(\exists S, S'. e \in E_S \wedge f \in E_{S'} \wedge S \xrightarrow{SO_{\mathcal{H}}} S' \wedge S' \approx_{\mathcal{H}} T \right)\}$$

Informally, $\boxed{T}_{\mathcal{H}}$ is the result of splicing all transactions in session of T into the same transaction.

Definition

For history \mathcal{H} , let

$$\text{splice}(\mathcal{H}) = \left(\{ \boxed{T}_{\mathcal{H}} \mid T \in \mathcal{T}_{\mathcal{H}} \}, \emptyset \right)$$

history resulting from splicing all sessions in a history.

- We'll call $\mathcal{G} \in \text{GraphSI}$ **spliceable** if exists a dependency graph $\mathcal{G}' \in \text{GraphSI}$ such that $\mathcal{H}_{\mathcal{G}'} = \text{splice}(\mathcal{H}_{\mathcal{G}})$.
- For graph \mathcal{G} we let $\approx_{\mathcal{G}} = \approx_{\mathcal{H}_{\mathcal{G}}}$.

Consider graph \mathcal{G} :

T', T : session transfer { tx { acct1 = acct1 - 100 }; tx { acct2 = acct2 + 100 } }
 T'' : session lookup1 { tx { return acct1 } }
 S'' : session lookup2 { tx { return acct2 } }
 S', S : session lookupAll { tx { var1 = acct1 }; tx { var2 = acct2 }; return var1 + var2 }

Example

The above graph is not spliceable:

- $T' \xrightarrow{\text{VIS}} S'$
- $\neg T \xrightarrow{\text{VIS}} S$
- $\boxed{T}_{\mathcal{G}} \xrightarrow{\text{WR}(\text{acct1})} \boxed{S}_{\mathcal{G}}$ but $\neg \boxed{T}_{\mathcal{G}} \xrightarrow{\text{WR}(\text{acct2})} \boxed{S}_{\mathcal{G}}$

Definition

Given \mathcal{G} let **dynamic chopping graph** $DCG(\mathcal{G})$ obtained from \mathcal{G} by

- Removing $WR_{\mathcal{G}}, WW_{\mathcal{G}}, RW_{\mathcal{G}}$ edges between transactions related by $\approx_{\mathcal{G}}$
- Adding SO^{-1} edges

We'll classify the edges as following:

- SO - **successor** edges
- SO^{-1} - **predecessor** edges
- $(WR_{\mathcal{G}} \cup WW_{\mathcal{G}} \cup RW_{\mathcal{G}}) \setminus \approx_{\mathcal{G}}$ - **conflict** edges

Definition

A cycle in $DCG(\mathcal{G})$ is **critical** if:

- Does not contain 2 occurrences of the same vertex
- Contains 3 consecutive edges in form of *conflict-predecessor-conflict*
- Any 2 anti dependency edges ($RW_{\mathcal{G}} \setminus \approx_{\mathcal{G}}$) are separated by at least one read ($WR_{\mathcal{G}} \setminus \approx_{\mathcal{G}}$) or write ($WW_{\mathcal{G}} \setminus \approx_{\mathcal{G}}$) dependency edge

Intuitively, we want criteria for $DCG(\mathcal{G})$ that translates into an invalid cycle on the spliced graph.

Consider \mathcal{G}

T', T : session transfer { tx { acct1 = acct1 - 100 }; tx { acct2 = acct2 + 100 } }
 T'' : session lookup1 { tx { return acct1 } }
 S'' : session lookup2 { tx { return acct2 } }
 S', S : session lookupAll { tx { var1 = acct1 }; tx { var2 = acct2 }; return var1 + var2 }

Example

$DCG(\mathcal{G})$ contains a critical cycle:

$$S' \xrightarrow{SO_{\mathcal{G}}} S \xrightarrow{RW_{\mathcal{G}}} T \xrightarrow{SO_{\mathcal{G}}^{-1}} T' \xrightarrow{WR_{\mathcal{G}}} S'$$

Theorem

For $\mathcal{G} \in \text{GraphSI}$, if $\text{DCG}(\mathcal{G})$ contains no critical cycles, then \mathcal{G} is spliceable.

Specifically:

- If \mathcal{G} is spliceable, then the spliced graph $\mathcal{G}' \in \text{GraphSI}$
- $\Rightarrow \mathcal{G}' \in \text{GraphSI}$ so it contains no cycles without adjacent anti-dependencies
- \Rightarrow we might be able to chop \mathcal{G}' into \mathcal{G}

We use the last theorem to derive the static analysis.

- Assume set of **programs** $\mathcal{P} = \{P_1, P_2, \dots\}$, each defining code of a session resulting from chopping a single transaction.
- Each P_i is composed of k_i **program pieces**
- W_j^i and R_j^i sets of objects written or read by j-th piece of P_i

- History \mathcal{H} **can be produced** by programs \mathcal{P} if there's 1:1 correspondence between every session in \mathcal{H} and program $P_i \in \mathcal{P}$, and each transaction in the session corresponds to respective program piece, along with its read/write sets.
- Chopping is defined **correct** if every dependency graph $\mathcal{G} \in \text{GraphSI}$, where $\mathcal{H}_{\mathcal{G}}$ can be produced by \mathcal{P} is spliceable.

T', T : session transfer { tx { acct1 = acct1 - 100 }; tx { acct2 = acct2 + 100 } }
 T'' : session lookup1 { tx { return acct1 } }
 S'' : session lookup2 { tx { return acct2 } }
 S', S : session lookupAll { tx { var1 = acct1 }; tx { var2 = acct2 }; return var1 + var2 }

Example

We have 4 *programs*, one for each session. Each transaction is a *program piece*.

For `transfer` session we have 2 program pieces with

- $T' : W_1^1 = R_1^1 = \{\text{acct1}\}$
- $T : W_2^1 = R_2^1 = \{\text{acct2}\}$

Consider program set \mathcal{P}

Definition

Static chopping graph $SCG(\mathcal{P})$ is a graph where nodes are program pieces in form of (i, j) and the edge $(i_1, j_1), (i_2, j_2)$ is present if:

- $i_1 = i_2$ and:
 - $j_1 < j_2$ (a **successor** edge)
 - $j_1 > j_2$ (a **predecessor** edge)
- $i_1 \neq i_2$ and:
 - $W_{j_1}^{i_1} \cap R_{j_2}^{i_2} \neq \emptyset$ (a **read dependency** edge)
 - $W_{j_1}^{i_1} \cap W_{j_2}^{i_2} \neq \emptyset$ (a **write dependency** edge)
 - $R_{j_1}^{i_1} \cap W_{j_2}^{i_2} \neq \emptyset$ (an **anti dependency** edge)

- The edge set of static graphs $SCG(\mathcal{P})$ over-approximate the edge sets of the dynamic graphs $DCG(\mathcal{G})$ corresponding to graphs \mathcal{G} produced by programs \mathcal{P} .
- The chopping defined by \mathcal{P} is correct if $SCG(\mathcal{P})$ contains no critical cycles (as defined for dynamic graphs).

Figure 5: The static chopping graph of the programs $\{\text{transfer}, \text{lookupAll}\}$ from Figure 4. Dashed boxes group program pieces into sessions.

Example

Fig. 5 contains a critical cycle:

$$\begin{aligned}
 &(\text{var1} = \text{acct1}) \xrightarrow{\text{RW}} (\text{acct1} = \text{acct1} - 100) \xrightarrow{\text{S}} \\
 &(\text{acct2} = \text{acct2} + 100) \xrightarrow{\text{WR}} (\text{var2} = \text{acct2}) \xrightarrow{\text{P}} (\text{var1} = \text{acct1})
 \end{aligned}$$

\Rightarrow not a valid chopping

Figure 6: The static chopping graph of the programs $\{\text{transfer}, \text{lookup1}, \text{lookup2}\}$ from Figure 4.

Example

Fig. 6 contains a single cycle, where two vertices appear twice \Rightarrow not a critical cycle. The above chopping is spliceable.

1 Introduction

2 Snapshot Isolation

- Definitions
- Dependency Graphs
- Characterization

3 Static Analysis

- Transaction Chopping
- **Robustness**

Robustness:

We'll derive an analysis that check where an application behaves the same way under a weak consistency model as it does under a strong one.

Robustness against SI towards SER

- Check if a given application running under **SI**, behaves the same as if it runs under **serializability** model.
- Specifically, no histories in $HistSI \setminus HistSER$

Theorem

For any \mathcal{G} , we have $\mathcal{G} \in \text{GraphSI} \setminus \text{GraphSER}$ iff. $\mathcal{T}_{\mathcal{G}} \models \text{INT}$, \mathcal{G} contains a cycle, and all its cycles have at least two adjacent anti-dependency edges.

Consider \mathcal{G} :

Example

The above graph contains a cycle with two adjacent anti-dependencies.

$\Rightarrow \mathcal{G} \in \text{GraphSI} \setminus \text{GraphSER}$

Static analysis:

- Assume code of transactions defined by set of programs \mathcal{P} with given read and write sets.
- Based on them, derive **static dependency graph**, over-approximating possible dependencies that can exist.
- Check that static dependency graph contains no cycles with two adjacent anti-dependency edges.

Robustness against PSI towards SI

- Check if a given application running under **PSI**, behaves the same as if it runs under **SI** model.
- Again, make sure there are no histories in $HistPSI \setminus HistSI$

Definition

Sets of executions and histories **allowed by parallel SI** are:

$$\begin{aligned} \textit{ExecPSI} &= \{ \mathcal{X} \mid \mathcal{X} \models \text{INT} \wedge \text{EXT} \wedge \text{SESSION} \wedge \\ &\quad \text{TRANSVIS} \wedge \text{NOCONFLICT} \} \\ \textit{HistPSI} &= \{ \mathcal{H} \mid \exists \text{VIS}, \text{CO}. (\mathcal{H}, \text{VIS}, \text{CO}) \in \textit{ExecPSI} \} \end{aligned}$$

(c) Long fork.

Definition

TRANSVIS axiom ensures that transactions ordered by *VIS* are observed by others in this order. However, allows transactions unrelated by *VIS* to be observed in different orders; in particular, allows *long fork* anomaly.

Theorem

Let

$$\text{GraphPSI} = \{ \mathcal{G} \mid (\mathcal{T}_{\mathcal{G}} \models \text{INT}) \wedge \\ \left(\left((SO_{\mathcal{G}} \cup WR_{\mathcal{G}} \cup WW_{\mathcal{G}})^+ ; RW_{\mathcal{G}}^? \right) \text{ is irreflexive} \right) \}$$

Then

$$\text{HistPSI} = \{ \mathcal{H} \mid \exists WR, WW, RW. (\mathcal{H}, WR, WW, RW) \in \text{GraphPSI} \}$$

Theorem

For any \mathcal{G} , we have $\mathcal{G} \in \text{GraphPSI} \setminus \text{GraphSI}$ iff. $\mathcal{T}_{\mathcal{G}} \models \text{INT}$, \mathcal{G} contains at least one cycle with no adjacent anti-dependency edges, and all its cycles have at least two anti dependency edges.

Static analysis:

- *Static dependency graph* contains no cycles where there are at least two anti-dependency edges and no two anti-dependency edges are adjacent.

Thank you!
